Noccaea caerulescens (J. & C. Presl) F.K. Mey Alpine Penny-cress

Native

GB & England: Least Concern

GB Scarce

VC5 Absent; VC6 Scarce

A glabrous rosette-forming perennial found in bare stony places or grassland, mostly on the metalliferous soils and spoil of former lead- or zinc-mining areas, although occasionally on non-metalliferous limestone outcrops and scree. In Somerset, always associated with former lead or calamine (zinc) workings and restricted to a discreet area of the Mendips. First recorded on Mendip in 1875 by C.E. Broome, it is still to be found at most of the locations mentioned by Murray (1896) and White (1912), although there are no recent records immediately around Sidcot. There are large populations easily visible at Priddy Mineries and at Blackmoor Nature Reserve near Charterhouse: at both sites many plants can be seen on piles of glassy black slag which resulted from Victorian re-smelting of lead mining waste. Murray (1896) observed that "It is fond of growing on the top of anthills, probably because of their greater dryness. It also affects the sides of the shallow calamine pits; where, being sheltered, it grows much more luxuriantly." Away from piles of slag, these are still the habitats where it is most likely to occur. Interestingly, neither Murray nor White (1912) mentioned piles of slag as a habitat, perhaps because at that time the deposits of slag were still unsuitable for colonisation. Indeed, Priddy Mineries was still an active site of industry until 1908; the first record of *Noccaea caerulescens* from that site is a specimen in **BM** collected by N. Wycherley in 1957. This species has a disjunct distribution, with sites also in west and north Wales, the Peak District, northern England and a few in Scotland. In Somerset it is at its most southerly location in Britain, 200km south of the next nearest population in England.
